RFC 206 - Asynchronous Services

Draft

34 Pages

Abstract

10 point Arial Centered.

The OSGi service registry is used by bundles to collaborate using loosely coupled services, registered with one or more public interfaces that can be called. OSGi services are, like most Java objects, normally designed to be called synchronously. There are, however, often significant advantages that can be realized by clients when they execute one or more parts of their operation asynchronously. This RFC provides a generic mechanism that allows existing OSGi services with a synchronous API to be invoked asynchronously without requiring them to be modified.

DISTRIBUTION AND FEEDBACK LICENSE, Version 2.0

The OSGi Alliance hereby grants you a limited copyright license to copy and display this document (the “Distribution”) in any medium without fee or royalty. This Distribution license is exclusively for the purpose of reviewing and providing feedback to the OSGi Alliance. You agree not to modify the Distribution in any way and further agree to not participate in any way in the making of derivative works thereof, other than as a necessary result of reviewing and providing feedback to the Distribution. You also agree to cause this notice, along with the accompanying consent, to be included on all copies (or portions thereof) of the Distribution. The OSGi Alliance also grants you a perpetual, non-exclusive, worldwide, fully paid-up, royalty free, limited license (without the right to sublicense) under any applicable copyrights, to create and/or distribute an implementation of the Distribution that: (i) fully implements the Distribution including all its required interfaces and functionality; (ii) does not modify, subset, superset or otherwise extend the OSGi Name Space, or include any public or protected packages, classes, Java interfaces, fields or methods within the OSGi Name Space other than those required and authorized by the Distribution. An implementation that does not satisfy limitations (i)-(ii) is not considered an implementation of the Distribution, does not receive the benefits of this license, and must not be described as an implementation of the Distribution. "OSGi Name Space" shall mean the public class or interface declarations whose names begin with "org.osgi" or any recognized successors or replacements thereof. The OSGi Alliance expressly reserves all rights not granted pursuant to these limited copyright licenses including termination of the license at will at any time.

EXCEPT FOR THE LIMITED COPYRIGHT LICENSES GRANTED ABOVE, THE OSGi ALLIANCE DOES NOT GRANT, EITHER EXPRESSLY OR IMPLIEDLY, A LICENSE TO ANY INTELLECTUAL PROPERTY IT, OR ANY THIRD PARTIES, OWN OR CONTROL. Title to the copyright in the Distribution will at all times remain with the OSGi Alliance. The example companies, organizations, products, domain names, e-mail addresses, logos, people, places, and events depicted therein are fictitious. No association with any real company, organization, product, domain name, email address, logo, person, place, or event is intended or should be inferred.

THE DISTRIBUTION IS PROVIDED "AS IS," AND THE OSGi ALLIANCE (INCLUDING ANY THIRD PARTIES THAT HAVE CONTRIBUTED TO THE DISTRIBUTION) MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, NON-INFRINGEMENT, OR TITLE; THAT THE CONTENTS OF THE DISTRIBUTION ARE SUITABLE FOR ANY PURPOSE; NOR THAT THE IMPLEMENTATION OF SUCH CONTENTS WILL NOT INFRINGE ANY THIRD PARTY PATENTS, COPYRIGHTS, TRADEMARKS OR OTHER RIGHTS.
NEITHER THE OSGi ALLIANCE NOR ANY THIRD PARTY WILL BE LIABLE FOR ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF OR RELATING TO ANY USE OR DISTRIBUTION OF THE DISTRIBUTION.

Implementation of certain elements of this Distribution may be subject to third party intellectual property rights, including without limitation, patent rights (such a third party may or may not be a member of the OSGi Alliance). The OSGi Alliance is not responsible and shall not be held responsible in any manner for identifying or failing to identify any or all such third party intellectual property rights.

The Distribution is a draft. As a result, the final product may change substantially by the time of final publication, and you are cautioned against relying on the content of this Distribution. You are encouraged to update any implementation of the Distribution if and when such Distribution becomes a final specification.

The OSGi Alliance is willing to receive input, suggestions and other feedback (“Feedback”) on the Distribution. By providing such Feedback to the OSGi Alliance, you grant to the OSGi Alliance and all its Members a non-exclusive, non-transferable,

worldwide, perpetual, irrevocable, royalty-free copyright license to copy, publish, license, modify, sublicense or otherwise distribute and exploit your Feedback for any purpose. Likewise, if incorporation of your Feedback would cause an implementation of the Distribution, including as it may be modified, amended, or published at any point in the future ("Future Specification"), to necessarily infringe a patent or patent application that you own or control, you hereby commit to grant to all implementers of such Distribution or Future Specification an irrevocable, worldwide, sublicenseable, royalty free license under such patent or patent application to make, have made, use, sell, offer for sale, import and export products or services that implement such Distribution or Future Specification. You warrant that (a) to the best of your knowledge you have the right to provide this Feedback, and if you are providing Feedback on behalf of a company, you have the rights to provide Feedback on behalf of your company; (b) the Feedback is not confidential to you and does not violate the copyright or trade secret interests of another; and (c) to the best of your knowledge, use of the Feedback would not cause an implementation of the Distribution or a Future Specification to necessarily infringe any third-party patent or patent application known to you. You also acknowledge that the OSGi Alliance is not required to incorporate your Feedback into any version of the Distribution or a Future Specification.

I HEREBY ACKNOWLEDGE AND AGREE TO THE TERMS AND CONDITIONS DELINEATED ABOVE.

Initial	08/11/13	Tim Ward – Initial version of RFC

1 Introduction

OSGi Bundles collaborate using loosely coupled services registered in the OSGi service registry. This is a powerful and flexible model, and allows for the dynamic replacement of services at runtime. OSGi services are therefore a very common interaction pattern within OSGi.

As with most Java APIs and Objects, OSGi services are primarily synchronous in operation. This has several benefits; synchronous APIs are typically easier to write and to use than asynchronous ones; synchronous APIs provide immediate feedback; synchronous implementations typically have a less complex threading model.

Asynchronous APIs, however, have different advantages. Asynchronous APIs can reduce bottlenecks by encouraging more effective use of parallelism, improving the responsiveness of the application. This intent of this RFC is to allow clients to get the benefits of asynchronous invocation, even when the Service API has been written in a synchronous way.

2 Application Domain

This section explores various aspects of adding support for asynchronous execution. Asynchronous execution typically is achieved via the introduction of a queuing mechanism for “tasks” which are pulled in and executed by one or more Threads. In the case of remote invocations, the task queue is often on the remote machine, allowing the request to be sent and executed without occupying a local Thread. These mechanisms are often also used to handle events, for example the OSGi Event Admin Service provides an asynchronous communication model.

Synchronous invocations are typically easier to program, but once a client makes a request, either local or remote, the client is blocked waiting for execution to complete and return control to the client. While asynchronous execution may be more complex to program, it offers many benefits and advantages.

For example, synchronous remote invocations depend on the availability of the network during request execution. If a client or server fails during the execution of a request, the request typically has to be resubmitted. This may not be a problem for some applications, where it’s easy to re-create the request input. But for other applications, such as an ATM, gas pump, or electronic funds transfer, it may not be easy to recapture the input data and create another request message, and asynchronous protocols meet the requirement better. Even when it is possible to recreate a request message, it is not always easy to know at which point the server failed – i.e. whether or not an update was performed as a result of executing the request, and if so, whether performing the update a second time might cause data inconsistency. And in this case asynchronous protocols can also offer some advantages.

Synchronous invocations operate on a first-come, first-served scheduling mechanism (i.e. the computer has to process requests as they are made by the caller). This means that it’s not easy to treat some invocations with higher priority than others, although this is a common application requirement (for example, a bank wants to process the outstanding $1M deposits ahead of the $10 deposits near the end of the banking day). As they have work queues, asynchronous processing engines can process work in an arbitrary order if they choose.

2.1 Asynchronous programming models

A variety of asynchronous programming models and frameworks are successfully used in enterprise applications today, including ExecutorServices, Async EJBs, Async Servlets, Node.js, store-and-forward, pub-sub, and broadcast/multicast to name a few. These programming models assume that a task is visible to a program using one or more asynchronous submission mechanisms (for example, JMS) and that the program is responsible for explicitly creating or retrieving a response using the API and then may act upon it in a way that is visible to another program using the same API.

For example, a store and forward system has one program submitting a message to a queue using a SEND or SUBMIT command, and another program retrieving the message from a queue using a RECEIVE or DEQUEUE command from the asynchronous programming model API. The sending program is responsible for packing, or serializing, the message, and the receiving program is responsible for unpacking, or de-serializing the message. (Some APIs define a wire format while others do not.)

In each case, management utilities are required to configure the capabilities of the asynchronous implementation being used so that they are able to reject work when overloaded, make best use of the resources available, and to identify, report and resolve any errors that may occur.

2.2 Mixture of programming models

Many enterprise applications require both synchronous and asynchronous execution models for different types of IT functions. For a reserved ticket purchase, for example, it may be necessary to synchronize the database update with the reply to the user to indicate the ticket was purchased, since only one person can have a given seat. For a book purchase, however, it may be sufficient to reply to the user that the order was received, and that it would be fulfilled later. Some of the fulfillment operations for a book order might also use synchronous communications, for example to debit inventory while packing the order for shipment.

2.3 Terminology + Abbreviations

Client – Application code that wishes to call one or more OSGi services asynchronous

Target Service – A service that is to be called asynchronously by the client

Async Service – The OSGi service representing the Asynchronous Services implementation. Used by the client.

Async Proxy – A proxy object representing the target service, created by the Async Service

Success Callback – A callback made when an asynchronous invocation exits with a normal return value

Failure Callback – A callback made when an asynchronous invocation exits by throwing an exception

Always Callback – A callback that is made when an asynchronous invocation exits, regardless of how it exits.

Asynchronous Invocation – A single method call that is to be executed without blocking the requesting thread.

Asynchronous Task – An aggregate of one or more asynchronous invocations. The invocations that make up a task may run in parallel, or sequentially, or a mixture of both.

3 Problem Description

The current OSGi programming model for communications among components and bundles is based on the OSGi service interface, which implies a synchronous semantic (i.e. the client invokes on the interface and waits for the reply), and language objects as parameters. These characteristics are typical of local invocations and distributed RPC and meet many requirements, but we want to extend these capabilities to support asynchronous invocation.

3.1 Asynchronous Services

We propose that the EEG evaluate options for specifying Asynchronous invocation of services – specifically the ability for a client to issue an invocation on a service interface without waiting for completion, and relying on a later notification or polling to check completion and retrieve results. For illustration, a low-level equivalent of such a framework is provided in J2SE by the Future interface. Other technologies (such as CORBA) provide asynchronous 'one-way' support on their remote interfaces. There are significant design considerations involved

in selecting whether this may be defined within the “OSGi Services” architecture, and/or “Blueprint”, and/or Remote Services; and how a particular choice of solution relates to all three architectures.

4 Requirements

AS01 – The solution MUST provide a standard client-side API for making asynchronous invocations on existing, synchronous, OSGi services,where the invocation returns quickly and a return value can be obtained later.

AS02 – The solution MUST allow transparent delegation to services that are already implemented in an asynchronous fashion, therefore servicing the asynchronous requests through their own implementations.

AS03 – The solution MUST define a mechanism that allows service providers to advertise an asynchronous mode of operation if they support it.

AS04 – The solution MAY provide a synchronous client-side API to services which are implemented in an asynchronous fashion.

AS05 – The solution MUST allow for one-way (fire and forget) asynchronous services.

AS06 – The solution MUST support Promises, where invocations can be made that later return a value

AS07 – The solution SHOULD support callbacks when asynchronous executions complete, both successfully and unsuccessfully

AS08 – The solution MUST be applicable to both local OSGi Services as well as Remote OSGi Services.

AS09 – The solution MUST be fully backwards compatible with existing OSGi Service and Service Registry usage.

AS010 – The solution SHOULD be sympathetic to Java 8's lambda support, meaning callbacks should follow the Single Abstract Method principle where possible.

5 Technical Solution

In order for a client to make asynchronous invocations on a service there are several necessary steps. First it is necessary to identify the service to be invoked, which we shall refer to as the target service. In the absence of any

further support the client would then need to create a Runnable or Callable that invoked the target service, and then execute this using an Executor or by starting a new Thread.

Rather than having each client managing its own asynchronous Executor an Async Service can manage the execution of the asynchronous invocation. This requires the Async service to track the invocations made on the target service and to asynchronously service them. To support requrements AS06 and AS07 the Async service also needs to provide a mechanism to register callbacks, and to return a Future.

This requirement is similar to the requirements that mocking frameworks such as Mockito have. They track invocations on proxy objects so that the invocations can later be checked, or so that specific invocations can be configured to return particular values. The Async Service uses a similar pattern, where invocations on a proxy are used to register the asynchronous executions that should occur.

5.1 The Async Service

The Async service is the primary interaction point between a client and the Async Services implementation. An Async Services implementation must expose a service implementing the `org.osgi.service.async.Async` interface.

Clients obtain an instance of the Async Service using the normal OSGi service registry mechanism, either directly using the OSGi framework API, or using dependency injection.

Implementations of the Async service must be thread safe. They should be safe to use simultaneously across multiple clients and from multiple threads within the same client.

5.2 Async Proxies

When a client has chosen a target service, it can use the Async service to make an asynchronous invocation. The first step is to use the Async Service to create a proxy to the real service.

```
<T> T createAsyncProxy(ServiceReference<T> ref);
```

Example:

```
Async asyncService = ctx.getService(ctx.getServiceReference(Async.class));
ServiceReference<List> ref = ctx.getServiceReference(List.class);
List proxy = createAsyncProxy(ref);
```

When creating the Async Proxy object the Async Service should attempt to load all of the classes listed in the objectclass property of the service reference

The proxy object returned by the Async service should attempt to load all of the classes declared in the ServiceReference's objectclass property. The resulting proxy should implement all of the interfaces that can be loaded by the client bundle.

5.2.1 Class Proxying

Proxying Java interfaces can be easily achieved using the java.lang.reflect.Proxy class, however proxying class types requires more complex handling. If an Async service implementation supports class proxying then it should declare the service property `org.osgi.service.async.proxy.classes=true`. If class proxying is supported then the proxy object created by the Async service should also inherit from the lowest subclass listed in the target service's objectclass property. There are three reasons why the Async service may not be able to proxy a class type:

1. The lowest sub-type is final
2. The lowest sub-type has no zero-argument constructor
3. One or more public methods present in the type hierarchy (other than those declared by java.lang.Object) are final.

If any of these rules are violated then the Async service should fall back to interface-only proxying.

5.2.2 Async Proxy return types

When invoked the Async proxy should return rapidly (i.e. it should not perform blocking operations). The client should not attempt to interpret the returned value. The value may be null (or null-like in the case of primitives) or contain implementation specific information.

5.2.3 Thread safety

Whilst the Async Service itself must be thread safe, async proxy objects may not be. Clients should avoid sharing async proxy objects between threads if they wish to be portable between implementations.

5.3 Building simple tasks

Once a proxy has been created it can be used, in conjunction with the Async service, to build an asynchronous task.

5.3.1 Establishing a context

To begin an asynchronous task the client invokes a method on the asynchronous proxy. The client then passes the result of that invocation to the Async service to establish the asynchronous invocation as the “current context”. The context has an associated type, which is the return type of the asynchronous invocation (or the associated wrapper type for primitives and void).

Example:

```
Async asyncService = ctx.getService(ctx.getServiceReference(Async.class));
ServiceReference<List> ref = ctx.getServiceReference(List.class);
List proxy = createAsyncProxy(ref);
Future<Boolean> futureResult = asyncService
          .build(proxy.contains(“badEntry”));
```

At this point the Asynchronous task is not complete, and the asynchronous invocation will not have started. Establishing the context has two purposes:

- To register the method call made on the proxy as an asynchronous invocation in this task.
- To establish return type information for listener and completion methods

If there is an error establishing a context, for example a client calls the build method without having invoked the async proxy, then the Async service should throw an `AsyncException`.

Once a context has been established, clients can continue to build the asynchronous task in one of several ways:

5.3.2 Completing tasks

Once a client has established a context then they can “complete” building the task using either the `launch()` method or `asPromise()` method. The `launch()` method is used for “Fire and Forget” style invocations, while the `asPromise()` method returns a `java.util.concurrent.Future`, typed appropriately for the return type of the asynchronous invocation.

Once one of the “completion” methods has been invoked the asynchronous task should begin executing. The real service object should be obtained by the Async Service implementation by using the client's `BundleContext` to call `getService()` on the `ServiceReference` used to create the async proxy.

Example – Fire and Forget:

```
Async asyncService = ctx.getService(ctx.getServiceReference(Async.class));
ServiceReference<List> ref = ctx.getServiceReference(List.class);
List proxy = createAsyncProxy(ref);
asyncService.build(proxy.remove(“badEntry”)).launch();
```

Example – With a promise:

```
Async asyncService = ctx.getService(ctx.getServiceReference(Async.class));
ServiceReference<List> ref = ctx.getServiceReference(List.class);
List proxy = createAsyncProxy(ref);
Future<Boolean> futureResult = asyncService
            .build(proxy.contains(“badEntry”)).asPromise();
```

The `Future` returned by the asPromise() method must obey the Java contracts for Futures. It must:

- be thread safe,
- Implement a cancel method that should make a best-effort to cancel or prevent the execution of the asynchronous invocation.
- provide a blocking get methods which returns the result of the execution
- throw an ExecutionException from the get methods, wrapping the real failure, if the asynchronous invocation threw an Exception
- throw a CancellationException from the get methods if the Future was cancelled
- Provide methods for determining whether a Future is finished, and whether it has been cancelled.

5.3.3 Registering Callbacks

Having established a context, a client may register callbacks with the asynchronous services implementation.

There are three kinds of callback:

- Success Callbacks – these are called with the result of the asynchronous invocation, if it returned normally. Implements the `org.osgi.service.async.SuccessCallback` interface.

- Failure Callbacks – these are called with the exception thrown by the asynchronous invocation, if it returned exceptionally. Implements the `org.osgi.service.async.FailureCallback` interface.

- Always Callbacks – these are always called after the asynchronous invocation has completed. Always Callbacks will be made after any success or failure callbacks have been made. Implements the `org.osgi.service.async.AlwaysCallback` interface.

All three callback interfaces follow the Single Abstract Method principle, which means that they are able to be substituted for lambda expressions in Java 8.

Callbacks can be registered against the asynchronous invocation represented by the current context using the `onSuccess()`, `onFailure()` and `always()` methods:

Example:

```
Async asyncService = ctx.getService(ctx.getServiceReference(Async.class));
ServiceReference<List> ref = ctx.getServiceReference(List.class);
List proxy = createAsyncProxy(ref);
asyncService.build(proxy.remove(“badEntry”))
            .onSuccess(new MySuccessCallback())
            .onFailure(new MyFailureCallback())
            .always(new MyAlwaysCallback()).launch();
```

Callbacks may also be used in conjunction with the `asPromise()` method.

5.3.4 Establishing context for Void methods

In Java void methods have no return value, and therefore cannot return anything. This means that void methods cannot establish context in the same way that other methods do. Void methods therefore need to be declared in a different way, using an `org.osgi.service.async.VoidMethodCall`. This interface defines a single abstract method callback inside which the client can make the void method call. In Java 8 this can be simplified to a lambda expression that makes the void method call. Another option for the client is to break the fluency of the builder, and to call the void method as a separate statement.

Example – Anonymous Inner class:

```
Async asyncService = ctx.getService(ctx.getServiceReference(Async.class));
ServiceReference<List> ref = ctx.getServiceReference(List.class);
List proxy = createAsyncProxy(ref);
asyncService.build(new VoidMethodCall() {
     public void invokeVoid() { proxy.clear(); }
}).launch();
```

Example – Out of Line expression:

```
Async asyncService = ctx.getService(ctx.getServiceReference(Async.class));
ServiceReference<List> ref = ctx.getServiceReference(List.class);
List proxy = createAsyncProxy(ref);
proxy.clear()
```

```
asyncService.build((Void) null).launch();
```

Example – Lambda expression:

```
Async asyncService = ctx.getService(ctx.getServiceReference(Async.class));
ServiceReference<List> ref = ctx.getServiceReference(List.class);
List proxy = createAsyncProxy(ref);
asyncService.build(() -> proxy.clear()).launch();
```

SuccessCallbacks for void methods are passed null as the return argument from the method.

5.4 Building more complex tasks

Asynchronous tasks may consist of multiple distinct asynchronous invocations. The builder returned by the Async service (`org.osgi.service.async.AsyncBuilder`) therefore supports establishing a new asynchronous invocation context after any necessary callbacks have been registered:

5.4.1 Running in Parallel

Most commonly asynchronous invocations are used to run multiple tasks in parallel. This can be achieved using the `parallel()` method to establish a new context. Once a new context has been established any calls to `onSuccess()`, `onFailure()` or `always()` will be applied to the new context.

Any parallel asynchronous invocations in an Asynchronous task are eligible to be run in parallel with the preceding asynchronous invocation. Note that this does not mean that the tasks will definitely run in parallel, for example there may be insufficient worker threads available to run additional tasks.

Example:

```
Async asyncService = ctx.getService(ctx.getServiceReference(Async.class));
ServiceReference<List> ref = ctx.getServiceReference(List.class);
List proxy = createAsyncProxy(ref);
asyncService.build(proxy.contains("badEntry"))
            .onSuccess(new MySuccessCallback()) //Applies to "badEntry"
            .parallel(proxy.contains("goodEntry"))
            .onSuccess(new AnotherSuccessCallback()) // Applies to "goodEntry"
            .launch();
```

5.4.2 Running sequentially

Sometimes asynchronous invocations have an implicit ordering requirement. In this case a single task can be created that only starts running an invocation after the previous invocation has successfully completed. This is accomplished by using the `then()` method to establish a new context. This works in the same way as the `parallel()` method, but the new asynchronous invocation is only eligible to run after the previous task returns

Example:

```
Async asyncService = ctx.getService(ctx.getServiceReference(Async.class));
ServiceReference<List> ref = ctx.getServiceReference(List.class);
```

```
List proxy = createAsyncProxy(ref);
asyncService.build(proxy.remove(“badEntry”))
            .then(proxy.contains(“badEntry”))
            .onSuccess(new AnotherSuccessCallback()) // Applies to contains()
            .launch();
```

5.4.3 Waiting for previous invocations

Sometimes it is not enough to wait for a single asynchronous invocation to complete, and instead you need to wait for a group of tasks to complete before continuing. In this case the `afterAll()` method establishes a new asynchronous invocation context that is only eligible to execute after all previous asynchronous invocations have completed.

Example:

```
Async asyncService = ctx.getService(ctx.getServiceReference(Async.class));
ServiceReference<List> ref = ctx.getServiceReference(List.class);
List proxy = createAsyncProxy(ref);
asyncService.build(proxy.contains(“badEntry”))
            .onSuccess(new MySuccessCallback())
            .parallel(proxy.contains(“goodEntry”))
            .onSuccess(new AnotherSuccessCallback())
            .afterAll(proxy.addAll(Arrays.asList(“goodEntry”, “badEntry”))
            .launch();
```

5.4.4 Receiving multiple promises

Some clients that issue multi-invocation asynchronous tasks will wish to consume the results of their asynchronous invocations using the `Future` API. Therefore the `org.osgi.service.async.AsyncCompleter` interface defines an `asPromises()` method that completes the asynchronous task, returning a `List` of `Future` objects, representing the completions of each asynchronous invocation in the task. The order of the objects in the `List` is the same as the order in which the client created the asynchronous invocation contexts that make up the task.

Example:

```
Async asyncService = ctx.getService(ctx.getServiceReference(Async.class));
ServiceReference<List> ref = ctx.getServiceReference(List.class);
List proxy = createAsyncProxy(ref);
List<Future<?>> promises = asyncService.build(proxy.contains(“badEntry”))
            .parallel(proxy.contains(“goodEntry”))
            .parallel(proxy.contains(“anotherEntry”))
            .asPromises(); //List is in the order 'bad, good, another'
```

5.4.5 Registering aggregate callbacks

It can be useful for clients to receive notifications about the overall progress of an asynchronous task, rather than about its individual elements. To support this use case the `AsynchronousBuilder` interface declares the

`andFinally()` method, which establishes a special context. This context represents the entire asynchronous task, not just a single asynchronous invocation within the task. This means that any callbacks registered using `onSuccess()` or `always()` will be called when the entire task has completed. Success callbacks will be called with a null argument. Failure callbacks registered with `onFailure()` will receive callbacks immediately when any of the asynchronous invocations that make up the asynchronous task fail. This means that the failure callback may be called multiple times, possibly concurrently.

It is supported to use aggregate callbacks as well as callbacks on individual asynchronous invocations.

Example:

```
Async asyncService = ctx.getService(ctx.getServiceReference(Async.class));
ServiceReference<List> ref = ctx.getServiceReference(List.class);
List proxy = createAsyncProxy(ref);
List<Future<?>> promises = asyncService.build(proxy.contains(“badEntry”))
           .parallel(proxy.contains(“goodEntry”))
           .parallel(proxy.contains(“anotherEntry”))
           .andFinally().always(new AllChecksFinished())
           .asPromises(); //List is in the order 'bad, good, another'
```

5.5 Execution Failures

There are a variety of reasons that Asynchronous invocations may fail. In any of these cases the asynchronous invocation should fail with an `org.osgi.service.async.AsyncException`. This exception should be passed to any failure callbacks, and should be the cause of any `ExceutionException` thrown by `Future#get()`

- If the client bundle's bundle context becomes invalid before looking up the target service
- If the target service becomes unavailable before making the asynchronous invocation, or returns null on lookup
- If the Async service is unable to accept new work, for example it is in the process of being shut down.
- If the target service is unable to be invoked with the supplied arguments (this indicates a missing uses constraint)
- If a previous dependent invocation from a `then()` or `afterAll()` call failed by throwing an exception

If the target service is successfully invoked, but the method call throws an exception, then this should be passed to the failure callback without wrapping it. It should also be the cause of any `ExceutionException` thrown by `Future#get()`

5.6 Delegating to asynchronous implementations

Some service APIs are already asynchronous in operation, and others are partly asynchronous, in that some methods run asynchronously and others do not. There are also services which have a synchronous API, but could run asynchronously because they are a proxy to another service. A good example of this kind of service is a remote service. Remote services are local views of a remote endpoint, and depending upon the implementation of

the endpoint it may be possible to make the remote call asynchronously, optimizing the thread usage of any local asynchronous call.

Services that already have some level of asynchronous support can advertise this by implementing the `org.osgi.service.async.spi.AsyncDelegate` interface. This can be used by the asynchronous services implementation, or by the client directly, to indicate that a call made on the service should be processed asynchronously. The `AsyncDelegate` can be used as follows:

1. Cast the object to `AsyncDelegate`
2. Invoke the `registerCallbacks(SuccessCallback, FailureCallback)` method, holding on to the `Cancellable` returned by the invocation
3. On the same thread make the desired asynchronous invocation on the target service.
4. The `AsyncDelegate` should begin asynchronously executing the method, and return a garbage value to the caller. When asynchronous execution completes the `AsyncDelegate` should invoke the relevant callback method, depending on whether invocation returned normally, or threw an exception.
5. If at any point the `Cancellable` is cancelled then the `AsyncDelegate` should make a best-effort attempt to stop asynchronous execution of the task. If the asynchronous invocation from step 3 has not yet been made then the `AsyncDelegate` should discard the registered callbacks and return to “normal” operation.

Example

```
List service = ctx.getService(ctx.getServiceReference(List.class));
if(service instanceof AsyncDelegate) {
     Cancellable c = ((AsyncDelegate)service)
               .registerCallbacks(new MySuccess(), new MyFailure());
     service.contains(“badEntry”);
}
// Callbacks will occur on completion of the asynchronous work
// Work can be cancelled using c.cancel();
```

6 Data Transfer Objects

It is unclear whether Asynchronous Services would benefit from DTOs

Package Summary		Page
org.osgi.service.async		17
org.osgi.service.async.spi		31

Package org.osgi.service.async

Interface Summary		Page
AlwaysCallback	This callback is passed to `AsyncBuilder` by users when they wish to be notified about the completion of their tasks.	*18*
Async	The Asynchronous Execution Service, used to access an `AsyncBuilder` for creating asynchronous jobs and "asynchronous proxies" for use with the builder.	*19*
AsyncBuilder	A Builder for asynchronous executions.	*21*
AsyncCompleter		*25*
FailureCallback	This callback is passed to `AsyncBuilder` by users when they wish to be notified about failures in their execution.	*28*
SuccessCallback	This callback is passed to `AsyncBuilder` by users when they wishe to be notified about successful completion of their tasks.	*29*
VoidMethodCall	This interface is used with `Async` and `AsyncBuilder` when making asynchronous calls of void methods.	*30*

Exception Summary		Page
AsyncException	This Exception is passed to a `FailureCallback` or returned as the cause of an `ExecutionException` from `Future.get()` when there was a problem starting the Asynchronous task.	*27*

Interface AlwaysCallback

org.osgi.service.async

public interface **AlwaysCallback**

This callback is passed to AsyncBuilder by users when they wish to be notified about the completion of their tasks. It will be called when the task completes, regardless of whether it was successful or unsuccessful.

Method Summary		Page
void	**always**() Called by the Asynchronous Services runtime to notify that an asynchronous call completed.	18

Method Detail

always

void **always**()

Called by the Asynchronous Services runtime to notify that an asynchronous call completed. The task may, or may not, have been successful.

Interface Async

org.osgi.service.async

```
public interface Async
```

The Asynchronous Execution Service, used to access an AsyncBuilder for creating asynchronous jobs and "asynchronous proxies" for use with the builder. Typical usage:

```
Async async = ctx.getService(asyncRef);

ServiceReference<MyService> ref = ctx.getServiceReference(MyService.class);

MyService asyncProxy = async.createAsyncProxy(ref);

Future<BigInteger> result = async.build(asyncProxy.getSumOverAllValues())
                                 .asPromise();
```

Calls can be made in parallel, chained, and callbacks can be made. For more information about this usage see AsyncBuilder

---

Method Summary		Page
AsyncBuilder<Void>	**build**(VoidMethodCall call) Create an AsyncBuilder for building asynchronous executions.	20
AsyncBuilder<T>	**build**(T call) Create an AsyncBuilder for building asynchronous executions.	19
T	**createAsyncProxy**(org.osgi.framework.ServiceReference<T> ref) Create an asynchronous proxy for this service reference.	19

Method Detail

createAsyncProxy

```
T createAsyncProxy(org.osgi.framework.ServiceReference<T> ref)
```

Create an asynchronous proxy for this service reference. The proxy will implement all of the interfaces declared in the `org.osgi.framework.Constants.OBJECTCLASS` property of the `org.osgi.framework.ServiceReference`. Method calls made on this proxy will not invoke the real service, and will not block.

Returns:
An asynchronous proxy for use with the AsyncBuilder returned by this service

---

build

```
AsyncBuilder<T> build(T call)
                throws IllegalStateException
```

Create an AsyncBuilder for building asynchronous executions.

Parameters:
`call` - the return value of a method call made on an async proxy created by createAsyncProxy(ServiceReference)

Returns:
throws IllegalStateException if no calls have been made to an async proxy by the current thread

Throws:
`IllegalStateException`

---

build

```
AsyncBuilder<Void> build(VoidMethodCall call)
                  throws IllegalStateException
```

Create an `AsyncBuilder` for building asynchronous executions. Use this method when you wish to asynchronously call a void method.

Parameters:
`call` - A `VoidMethodCall` that invokes a void method on the async proxy object
Returns:
throws IllegalStateException if after calling `VoidMethodCall.invokeVoid()` no calls have been made to an async proxy by the current thread
Throws:
`IllegalStateException`

Interface AsyncBuilder

org.osgi.service.async

Type Parameters:

T - The current return type of the Asychronous task.

All Superinterfaces:

AsyncCompleter<T>

```
public interface AsyncBuilder
extends AsyncCompleter<T>
```

A Builder for asynchronous executions. It allows multiple tasks to be executed in parallel, or sequentially, or a mixture of both

---

Method Summary		Page
AsyncBuilder<Void>	**afterAll**(VoidMethodCall nextCall) Indicate that another asynchronous service call should be made, and that it may only begin to execute after the completion of all of the previous calls.	24
AsyncBuilder<V>	**afterAll**(V nextCall) Indicate that another asynchronous service call should be made, and that it may only begin to execute after the completion of all of the previous calls.	23
AsyncCompleter<T>	**always**(AlwaysCallback always) Register a callback that should be made when the current step of this task has completed.	22
AsyncCompleter<Void>	**andFinally**() Calling this method indicates to the framework that no new steps will be added to this task.	21
AsyncBuilder<T>	**onFailure**(FailureCallback onFailure) Register a callback that should be made if the current step of the asynchronous execution fails to complete successfully.	22
AsyncBuilder<T>	**onSuccess**(SuccessCallback<? super T> onSuccess) Register a callback that should be made if the current step of the asynchronous execution completes successfully.	22
AsyncBuilder<Void>	**parallel**(VoidMethodCall parallelCall) Indicate that another asynchronous service call should be made, and that it may execute in parallel with the current call.	23
AsyncBuilder<V>	**parallel**(V parallelCall) Indicate that another asynchronous service call should be made, and that it may execute in parallel with the current call.	22
AsyncBuilder<Void>	**then**(VoidMethodCall parallelCall) Indicate that another asynchronous service call should be made, and that it may only begin to execute after the completion of the current call.	23
AsyncBuilder<V>	**then**(V nextCall) Indicate that another asynchronous service call should be made, and that it may only begin to execute after the completion of the current call.	23

Methods inherited from interface org.osgi.service.async.AsyncCompleter
asPromise, asPromises, launch

Method Detail

andFinally

AsyncCompleter<Void> **andFinally**()

Calling this method indicates to the framework that no new steps will be added to this task. Calling this method changes the behaviour of subsequently added success and failure callbacks, which will now apply to the aggregate task as a whole.

Returns:
An AsyncCompleter that can be used to register callbacks for the entire asynchronous task

---

onSuccess

`AsyncBuilder<T> onSuccess(SuccessCallback<? super T> onSuccess)`

Register a callback that should be made if the current step of the asynchronous execution completes successfully.

Specified by:
`onSuccess` in interface `AsyncCompleter`
Parameters:
`onSuccess` - a callback that will be called with the value returned by this task if it has successfully completed

---

onFailure

`AsyncBuilder<T> onFailure(FailureCallback onFailure)`

Register a callback that should be made if the current step of the asynchronous execution fails to complete successfully.

Specified by:
`onFailure` in interface `AsyncCompleter`
Parameters:
`onFailure` - a callback that will be called if this task fails to complete successfully

---

always

`AsyncCompleter<T> always(AlwaysCallback always)`

Register a callback that should be made when the current step of this task has completed.

Specified by:
`always` in interface `AsyncCompleter`
Parameters:
`always` - a callback that will be called when all parts of this task have completed

---

parallel

`AsyncBuilder<V> parallel(V parallelCall)`

Indicate that another asynchronous service call should be made, and that it may execute in parallel with the current call. Whether or not this call does execute in parallel is determined by the number and availability of threads in the underlying implementation. Note that this call establishes a new AsyncBuilder context, meaning that any subsequent calls to `onFailure(FailureCallback)`, and related methods will be for the new execution result.

Returns:
An AsyncBuilder representing the new context

---

parallel

AsyncBuilder<Void> **parallel**(VoidMethodCall parallelCall)

Indicate that another asynchronous service call should be made, and that it may execute in parallel with the current call. Whether or not this call does execute in parallel is determined by the number and availability of threads in the underlying implementation. Note that this call establishes a new AsyncBuilder context, meaning that any subsequent calls to onFailure(FailureCallback), and related methods will be for the new execution result.

Returns:
An AsyncBuilder representing the new context

---

then

AsyncBuilder<V> **then**(V nextCall)

Indicate that another asynchronous service call should be made, and that it may only begin to execute after the completion of the current call. Note that execution of the new task is only blocked by the current task, other parallel executions may not have completed when the new task starts. If you wish to wait for all parallel tasks to complete then you should use the afterAll(Object) method. Note that this call establishes a new AsyncBuilder context, meaning that any subsequent calls to onFailure(FailureCallback), and related methods will be for the new execution result.

Returns:
An AsyncBuilder representing the new context

---

then

AsyncBuilder<Void> **then**(VoidMethodCall parallelCall)

Indicate that another asynchronous service call should be made, and that it may only begin to execute after the completion of the current call. Note that execution of the new task is only blocked by the current task, other parallel executions may not have completed when the new task starts. If you wish to wait for all parallel tasks to complete then you should use the afterAll(VoidMethodCall) method. Note that this call establishes a new AsyncBuilder context, meaning that any subsequent calls to onFailure(FailureCallback), and related methods will be for the new execution result.

Returns:
An AsyncBuilder representing the new context

---

afterAll

AsyncBuilder<V> **afterAll**(V nextCall)

Indicate that another asynchronous service call should be made, and that it may only begin to execute after the completion of all of the previous calls. have completed. Note that execution of the new task is blocked by all previous tasks Note that this call establishes a new AsyncBuilder context, meaning that any subsequent calls to onFailure(FailureCallback), and related methods will be for the new execution result.

Returns:
An AsyncBuilder representing the new context

---

afterAll

```
AsyncBuilder<Void> afterAll(VoidMethodCall nextCall)
```

Indicate that another asynchronous service call should be made, and that it may only begin to execute after the completion of all of the previous calls. have completed. Note that execution of the new task is blocked by all previous tasks Note that this call establishes a new AsyncBuilder context, meaning that any subsequent calls to `onFailure(FailureCallback)`, and related methods will be for the new execution result.

Returns:

An AsyncBuilder representing the new context

Interface AsyncCompleter

org.osgi.service.async

All Known Subinterfaces:
AsyncBuilder

```
public interface AsyncCompleter
```

Method Summary		Page
AsyncCompleter<T>	**always**(AlwaysCallback always) Register a callback that should be made when all steps of this task have completed.	26
Future<T>	**asPromise**() Complete building this asynchronous task, returning a Future that can be used to obtain the result of the asynchronous execution.	25
List<Future<?>>	**asPromises**() Complete building this asynchronous task, returning a list of Futures that can be used to obtain the results of the component parts of this asynchronous execution.	25
void	**launch**() Complete building this asynchronous task, enabling it to be run.	25
AsyncCompleter<T>	**onFailure**(FailureCallback onFailure) Register a callback that should be made if any step of the aggregate task fails to complete successfully.	26
AsyncCompleter<T>	**onSuccess**(SuccessCallback<? super T> onSuccess) Register a callback that should be made if all steps of this aggregate task complete successfully	26

Method Detail

launch

```
void launch()
```

Complete building this asynchronous task, enabling it to be run.

---

asPromise

```
Future<T> asPromise()
```

Complete building this asynchronous task, returning a Future that can be used to obtain the result of the asynchronous execution. If there were multiple parts to this execution then this Future will only represent the state of the final task. When it `Future.isDone()` it does not necessarily indicate that other parallel tasks have completed.

Returns:
The result of the final asynchronous invocation in this task as a Future

---

asPromises

```
List<Future<?>> asPromises()
```

Complete building this asynchronous task, returning a list of Futures that can be used to obtain the results of the component parts of this asynchronous execution.

Returns:
A List containing promises for each asynchronous invocation in the asynchronous task, in the order they were declared when building the task.

---

onSuccess

`AsyncCompleter<T> onSuccess(SuccessCallback<? super T> onSuccess)`

Register a callback that should be made if all steps of this aggregate task complete successfully

Parameters:
`onSuccess` - a callback that will be called with the value `null` if all parts of this task successfully complete

---

onFailure

`AsyncCompleter<T> onFailure(FailureCallback onFailure)`

Register a callback that should be made if any step of the aggregate task fails to complete successfully.

Parameters:
`onFailure` - a callback that will be called when any part of this task fails to complete successfully

---

always

`AsyncCompleter<T> always(AlwaysCallback always)`

Register a callback that should be made when all steps of this task have completed.

Parameters:
`always` - a callback that will be called when all parts of this task have completed

Class AsyncException

org.osgi.service.async

```
java.lang.Object
  └java.lang.Throwable
      └java.lang.Exception
          └java.lang.RuntimeException
              └org.osgi.service.async.AsyncException
```

All Implemented Interfaces:
Serializable

```
public class AsyncException
extends RuntimeException
```

This Exception is passed to a `FailureCallback` or returned as the cause of an `ExecutionException` from `Future.get()` when there was a problem starting the Asynchronous task. This may be because the backing service was unregistered, or because the Asynchronous implementation was unable to accept any more work. This Exception should not be used to wrap Exceptions thrown by the service execution. These should be given directly to the `FailureCallback` or set as the cause of an `ExecutionException` when using `Future.get()`

Constructor Summary	Page
AsyncException()	27
AsyncException(String message)	27
AsyncException(String message, Throwable cause)	27
AsyncException(Throwable cause)	27

Constructor Detail

AsyncException

```
public AsyncException()
```

AsyncException

```
public AsyncException(String message,
                      Throwable cause)
```

AsyncException

```
public AsyncException(String message)
```

AsyncException

```
public AsyncException(Throwable cause)
```

Interface FailureCallback

org.osgi.service.async

public interface **FailureCallback**

This callback is passed to AsyncBuilder by users when they wish to be notified about failures in their execution.

Method Summary		Page
void	**failure**(Throwable t) Called by the Asynchronous Services runtime to notify that an asynchronous call failed to complete normally.	28

Method Detail

failure

void **failure**(Throwable t)

Called by the Asynchronous Services runtime to notify that an asynchronous call failed to complete normally. This may mean that the task could not be called at all, or that it threw an Exception while running.

Interface SuccessCallback

org.osgi.service.async

public interface **SuccessCallback**

This callback is passed to AsyncBuilder by users when they wishe to be notified about successful completion of their tasks.

Method Summary		Page
void	**success**(T returnValue) Called by the Asynchronous Services runtime to notify that an asynchronous call completed normally.	29

Method Detail

success

void **success**(T returnValue)

Called by the Asynchronous Services runtime to notify that an asynchronous call completed normally.

Parameters:

returnValue - The value returned by the asynchronous call. This will be null for void method executions.

Interface VoidMethodCall

org.osgi.service.async

```
public interface VoidMethodCall
```

This interface is used with Async and AsyncBuilder when making asynchronous calls of void methods. Usage example:

```
Async async = ctx.getService(asyncRef);

ServiceReference<MyService> ref = ctx.getServiceReference(MyService.class);

MyService asyncProxy = async.createAsyncProxy(ref);

async.build(asyncProxy.sendConfirmationEmail(customerEmail, orderNumber).launch();
```

Method Summary		Page
void	**invokeVoid**() This method is invoked by the Async service to determine which method should be asynchronously invoked	30

Method Detail

invokeVoid

```
void invokeVoid()
```

This method is invoked by the Async service to determine which method should be asynchronously invoked

Package org.osgi.service.async.spi

Interface Summary		Page
AsyncDelegate	This interface is used by services to allow them to optimize Asynchronous calls where they are capable of executing more efficiently.	32
Cancellable		33

Interface AsyncDelegate

org.osgi.service.async.spi

`public interface` **`AsyncDelegate`**

This interface is used by services to allow them to optimize Asynchronous calls where they are capable of executing more efficiently. This may mean that the service has access to its own thread pool, or that it can delegate work to a remote node, or act in some other way to reduce the load on the Asynchronous Services implementation when making an asynchronous call.

Method Summary		Page
Cancellable	**registerCallbacks**(SuccessCallback<?> success, FailureCallback failure) This method can be used by the Async service to optimize Asynchronous execution.	32

Method Detail

registerCallbacks

```
Cancellable registerCallbacks(SuccessCallback<?> success,
                              FailureCallback failure)
```

This method can be used by the Async service to optimize Asynchronous execution. When called, the AsyncDelegate should begin tracking the thread that invoked this method, and store away the supplied callbacks. The next invocation made on this service by the tracked thread should be executed asynchronously (immediately returning a garbage value if necessary). When the asynchronous invocation completes the AsyncDelegate should call the relevant callback

Returns:

an object that may be used to 'cancel' the asynchronous execution. Cancellation is a best-effort operation, and may not halt the execution of a running operation.

Interface Cancellable

org.osgi.service.async.spi

public interface **Cancellable**

Method Summary		Page
void	**cancel**() Attempt to cancel this asynchronous execution.	33

Method Detail

cancel

void **cancel**()

Attempt to cancel this asynchronous execution. This may have no effect.

8 Considered Alternatives

9 Security Considerations

Asynchronous Services implementations must be careful to avoid elevating the privileges of client bundles when calling services asynchronously. This means that the implementation must:

- Use the client bundle to load interfaces when generating the asynchronous proxy. This prevents clients from gaining access to interfaces they would not normally be permitted to import.
- Use the client's bundle context when retrieving the target service. This prevents the client bundle from being able to make calls on a service object that they would normally be forbidden from obtaining.

Further security considerations can be addressed using normal OSGi security rules, access to the Async service can be controlled using ServicePermission[Async, GET].
