

RFP 196 OSGi Connect

Draft

7 Pages

Abstract

Discusses the needs for a specification that would make code and services from outside of an OSGi framework available to OSGi and vice versa.

1 Introduction

This RFP discusses the need for an OSGi Framework that can integrate externally defined modules which are outside of the control of the framework. In other words, to connect the OSGi Framework to code and services from the outside world like jars on the classpath or JPMS modules.

Parts of this work were first explored in RFP-143 OSGiConnect. Although RFP-143 got accepted it never made it into an RFC. This RFP is taking the basic idea and generalizes it to allow for an adjusted set of use cases as well as focusing on a design that could possibly be driven by an SPI.

2 Application Domain

The OSGi framework consists of a number of layers where the module layer is by far the largest and most complex. This layer has shownproved to be very useful for large and complex applications that require side by side versioning and encapsulation of their classes.

The OSGi module layer takes care of the class loading for each bundle and isolates bundles in their own class loader, minimizing global space. The consequence of the module layer being responsible for class loading, prevents or at least makes it very difficult to use classes or services that are already present on the class path and whichwhose class space is managed outside of OSGi.

Draft June 5, 2019

At the same time, functionality running outside of OSGi is not <u>easily</u> able to benefit from the rich service model of OSGi in a standardized way.

Finally, the OSGi framework assumes it is in control of the actual deployment units i.e., the jar files that get installed as Bundles. There is no way to represent outside content as bundles where the framework hasn't been given the deployment unit.

2.1 Terminology + Abbreviations

OSGi Connect - Working name given to this effort.

Connect Bundle – A connect bundle is a module provided from outside of the OSGi framework and represented within the OSGi framework as a bundle. A connect bundle is usually already fully wired and as its deployment unit isn't given to the framework, it can't be changed at runtime via the OSGi framework. Apart from that it can function as a proper bundle but might have some limitations with respect to class loading and isolation which need to be defined during the specification process.

3 Problem Description

There is a need for a solution that allows Java developers to connect an OSGi Framework to code running outside of the OSGi framework. This opens up OSGi to "normal" Java applications and allows to use OSGi functionality for dedicated use cases. At the same time, OSGi gets access to the outer world and is not losing any of its core functionality and benefits. Furthermore, if it would be possible to connect outside code to an OSGi Framework in such a way that it doesn't have to be in control of the actual deployment unit in order to represent it as a bundle, it could serve as a light weight service registry more easily. Finally, it would allow developers to create hybrid modules that can be used inside OSGi as well as in other contexts and would still work if the two are used within the same application.

4 Use Cases

bnd in Ant and Maven

bnd, the OSGi tool to make manifests, is an eclipse plugin, an ant task, a bundle, and a command line utility. Because it has to run inside Ant and Maven it cannot rely on the presence of an OSGi framework. For this reason, it sadly implements a plugin model based on class loaders. If a (light weight) OSGi was available that provided the OSGi service registry to outside code to allow to isolate bnd plugins, then bnd could carry this OSGi Connect in its Ant task and Maven plugin.

June 5, 2019

4.1 WARs

The Java EE is a highly popular format for deploying web applications. The different servlet bridges have made it possible to use OSGi inside the WARs but especially in Java EE based applications the class loading issues are prevalent. An OSGi Connect could be triggered when a servlet is loaded and thereby activating all "bundles" and let them collaborate through the service registry without the need to actually copy them into the framework cache.

4.2 Application Frameworks

Numerous application frameworks exist to provide convenient access to various services ranging from parsing, logging, and security to web access and persistence. The popularity or usefulness of a given framework could lead to it to be adopted and even relied upon by an application. Unfortunately, some frameworks have intrinsic dependencies and built-in assumptions about the classloader environment. In some cases these frameworks will not function correctly in OSGi. OSGi Connect is one way to enable applications to use some of the benefits of OSGi services and modules, but still be able to make use of existing frameworks.

4.3 Build a hybrid OSGi-JPMS application

A Java application may have some of it's functionality implemented as bundles and another part implemented as JPMS modules. It should be possible to use JPMS modules within an OSGi framework. This could make it possible to accurately reflect available system packages in a JPMS environment and would allow the framework to itself be a JPMS module. Ultimately, it could be possible to create JPMS modules that carry enough meta-data to work inside OSGi as well and vice versa where one could still use them inside OSGi even in case they are provided as JPMS modules in a given application.

4.4 Applications with a flat classpath Runnable fat jar

In some scenarios its common to package a Java application as a single jar with all the jars embedded. Usually a custom classloader is used to add all embedded jars to the classpath and then the application is launched. In these scenarios all jars/modules are already on the classpath and a contained OSGi framework does not need to provide module isolation and can directly use the jars as bundles, still providing most of the OSGi functionality.

4.5 Native compilation

In some scenarios, it is becoming common place that Java applications are compiled to native code AOT. In AOT compilation, custom classloaders can be a problem. This approach would potentially allow to make OSGi bundles work from the outside where they (together with the framework) are AOT compiled.

5 Requirements

5.1 Basic

BA0010 – It must be possible to install Connect Bundles. A connect bundle is an entity that is already on the class path of the framework.

Draft

June 5, 2019

- BA0020 It must be possible for Connect bundles to participate in the Service Layer as usual tfor Bundles. o add, update and remove services to/from the service registry from the outside of the framework.
- BA0030 It must be possible to use OSGi services implementing an API provided by a Connect Bundle outside of the OSGi framework.

5.2 Connect Bundle

- CB0010 It must be possible to provide the class loader for a connect bundle.
- CB0020 It must be possible to influence the wiring of a connect bundle <u>similar to existing resolver</u> hooks.
- CB0030 It must be possible to provide the manifest headers of a connect bundle.
- CB0040 It must be possible to provide the resources/entries of a connect bundle.
- CB0050 Connect bundles must be treated and behave like any other bundle except for a limited set of functionalities that are explicitly not supported.
- CB0060 Connect Bundles must be subject to the standard OSGi resolution rules.
- CB0070 All existing lifecycle methods must be well-defined wrt. Connect Bundles.
